Frozen Storage Studies of Composite Fish Mince From Dhoma (Sciaenid sp.) and Lactarius (Lactarius lactarius)

ANIL AGARWAL*, M. R. RAGHUNATH and K. K. SOLANKI Veraval Research Centre of Central Institute of Fisheries Technology, Veraval - 362 265.

Fish minces from Dhoma and Lactarius were mixed in the ratio of 40:60 respectively, and quick frozen along with individual minces at -40°C and stored at -20°C. Shelf-life was evaluated by following biochemical, physical and organoleptic changes occured during storage upto 44 weeks. Rapid decreases were noted in water soluble nitrogen and salt soluble nitrogen fractions during the initial period of 16 weeks. A good correlation was observed between changes in salt-soluble nitrogen and organoleptic evaluation. The minces were in good and acceptable condition up to 32 weeks of storage.

A large number of fish species caught in Indian trawlers as bycatch are sold as trash fish. No fish is intrinsically trash and that poor infrastructure for handling, storage, distribution and processing limits utilization of a portion of landed catch for direct human consumption (Menon & Samuel, 1975; Sripathy, 1977) and so the surplus catch goes for industrial reduction. Silver bellies, ribbon fish, cat fish, sciaenids, lactarius, shark, rays, soles etc. constitute the list of fishes that are generally considered as low priced fish in various parts of the country. Diversification is the only alternative to create a market for these low priced fish which compare favourably with table fish as far as nutritional aspects are concerned. There are several ways by which these low cost, under-utilized fish could be made use of as food rather than as feed. One such method 'Meat picking' to obtain boneless fish mince offer several advantages such as better yield, incorporation of stabilizers, flexibility in product presentation, low cost and possibility of blending. In tropical regions where trawler catches are of mixed composition and varied palatability, it is of interest to determine whether mixing minces from two different fishes yields an acceptable and stable product and whether such a blending can improve physical and organoleptic characters of a less palatable fish. Although in India, a lot of work has been done on the production of mince meat

and preparation of various products from it, (Menon & Samuel, 1975; Perigreen et al. 1979; Nair et al. 1982; Joseph & Perigreen 1983) reports on the possibilities and effects of mixing the minces from various fish are limited. The present paper is a report on the mixing minces from low priced dhoma and lactarius and their frozen storage characteristics.

Materials and Methods

Fresh dhoma and lactarius were procured from the local fish landing centre and immediately brought to the laboratory, washed thoroughly, iced and kept over night in

insulated boxes. Next day the fish were beheaded and eviscerated and dhoma were split open from the ventral side to expose maximum surface area, and the fish were thoroughly washed again. Minced meat was prepared by feeding both fish separately into a Baader-694 deboning machine. Minces from dhoma and lactarius were thoroughly mixed manually in the ratio of 40:60 respectively. Individual and mixed minces were spread evenly in freezing trays, lined

with 300 gauge LDPE sheets in which spacers were placed to get blocks of 500 g each. Trays were then covered with 300 gauge LDPE sheets and quick frozen in a plate freezer at-40°C. After freezing, the blocks were glazed, packed individually in 200 LDPE sheets, placed in master cartons and stored at -20°C. Fish minces were analysed for its changes in biochemical, physical and organoleptic parameters, just before and immediately after freezing and

then periodically up to 44 weeks. Physical and bio-chemical analysis of frozen samples were carried out on thawed meat. Frozen blocks were sealed in polythene bags and thawed in running water for 60 min and then drained for 20 min.

Moisture was determined by AOAC methods (1975), total nitrogen (TN) and water soluble nitrogen (WSN) by microkjeldahl method, salt soluble nitrogen (SSN) by the method of Dyer (1950). For organoleptic studies the frozen blocks were cut into 4.0 x 1.5 x 1.5 cm sizes approximately and dipped in whole egg batter with 4% salt (w/w), rolled in rice samoline containing 2% salt and deep fried in ground nut oil to a golden brown colour. Organoleptic quality of the fried samples were rated by a taste panel.

Results and Discussions

The yield of minced meat from dhoma and lactarius were 50% and 65% respectively of the whole fish. Mince meat from dhoma had a attractive pinkish white colour where as lactarius mince had a whitish grey colour while mixed mince had a greyish white colour with a pink tinge.

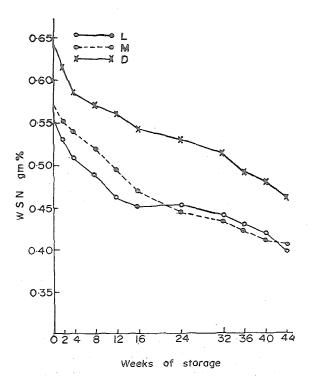

Fig. 2. Changes in water soluble nitrogen during frozen storage at -20°C.

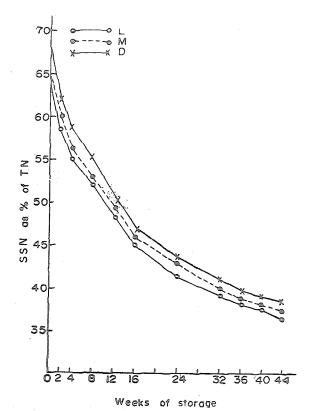

Fig. 3. Changes in salt soluble nitrogen during frozen storage at -20°C.

The changes in physical characteristics of thawed meat during the course of frozen storage are given in Table 1. It is observed that in physical characteristics mixed mince is at par with that of lactarius and rated higher than dhoma throughout the storage period.

Changes is moisture content of the minces during frozen storage are given in Fig. 1. A slight decrease in the moisture content throughout the storage period was observed in all the minces. The relatively low moisture loss can be attributed to the effective packing of the frozen mince blocks, by glazing wrapping in polythene sheets and storing in master cartons. Changes in WSN fractions of the minces during the frozen storage are shown in Fig. 2. Dhoma mince had a higher initial WSN content and this difference continued throughout the storage period. A decreasing trend in WSN was observed in all the three minces with higher rate of decrease during the first 24 weeks of storage. Subsequent rate of decrease though much less pronounced was higher for dhoma than for lactarius and mixed. Fig. 3 represents the changes

in SSN fractions of the minces during frozen storage. Dhoma mince had a higher initial salt solubility than lactarius and mixed mince which was maintained throughout the storage period. Initial decreases in SSN were fairly rapid up to 16 weeks of storage, followed a gradual decrease in the subsequent period up to 32 weeks. After this period the solubility losses were very low and reached almost to a constant level. Similar decreasing trends were observed in frozen storage of threadfin bream mince (Joseph & Perigreen, 1983).

The results of sensory evaluation are presented in Table 2. Lactarius mince received consistently higher ratings followed by mixed and dhoma. Organoleptic qualities were found to decrease rather rapidly in the

first 16 weeks followed by a marginal reduction in the quality up to 32 weeks of storage. A second reduction in quality was noted after this period. Such a decrease in organoleptic quality at a later stage in frozen storage could be due to the textural changes in the minces which have been shown to occur in frozen fish mince long after their salt solubilities have reached a constant level (Rodger et al. 1979). A good correlation was observed between organoleptic quality and changes in salt solubilities of minces.

The shelf life of Dhoma mince as shown by the physical and organoleptic evaluation, was in good condition up to 16 weeks and in fair and acceptable condition up to 24 weeks of storage, while the lactarius mince and mixed mince were found to be in good condition up to 16 weeks and in fair and acceptable condition up to 32 weeks of storage.

It is observed from Tables 1 and 2, that the mixed mince in physical and organoleptic character is closer to that of lactarius than dhoma and definitely got higher ratings over dhoma mince. Thus blending of dhoma mince with that of lactarius not only yields a stable product but also to a certain extent, improve the physical and organoleptic character of dhoma.

The authors are grateful to Dr. P.G.V. Nair, Scientist-in-charge, Veraval Research Centre of CIFT, Veraval, for critically going through this paper. The authors also expresses their sincere thanks to Shri M.R. Nair, Director, Central Institute of Fisheries Technology, Cochin - 682 029 for granting permission to publish the paper. The help rendered by Shri T. Gangadharan and Shri K. U. Shekh is also acknowledged.
