ABSTRACT

The present investigation was carried out to find out the response of plant growth regulators on the growth, yield and quality of the papaya fruits were significantly influenced by plant growth regulators studied. Among treatments, the highest vegetative growth, yield attributing characters and yield were recorded with GA₃ 200 ppm. It also recorded maximum value with respect to different growth parameters, viz. plant height, girth and E-W and N-S spread. Treatment with 200 ppm GA₃ also showed superiority in different yield-attributing characteristics, such as fruit set percentage, number of fruits/plant, fruit length, fruit diameter, fruit circumference, fruit weight, and fruit volume. Quality parameters, such as TSS, acidity, total, reducing and non-reducing sugars of fruits, 400 ppm of ethrel, exhibited significantly maximum value.

Key words: Growth, Papaya, Plant growth regulators, Quality, Yield

Papaya (Carica papaya L.) is considered as one of the commercial fruit crop of tropical and sub-tropical region because of high remuneration, nutritional and medicinal values. It has emerged from the status of a home garden plant to that of commercial orchards because of the availability of fruits throughout the year, ease of cultivation and the quick returns (Drew et al. 1998).

The use of plant growth regulators has assumed an integral part of modern fruit production to improve the quality and production of fruits, and it has resulted in outstanding achievements in a number of fruit crops with regard to improvements in yield and quality (Jain and Dashora 2011). Because of its diverse effects, it is possible to use certain growth regulating chemicals at particular stages of fruit growth and development to exhibit maximum effects. Occasionally, they are needed to be supplemented exogenously for additional stimulus for plants such as papaya, which require quick responses for increased growth, fruit set and yield (Singh and Singh 2009). Considering all of these facts, a pressing need exists to lay out a field experiment to study the influence of plant growth regulators on the growth, yield and physico-chemical characteristics of papaya cv. Red Lady in Mizoram, north-east India.

MATERIALS AND METHODS

The present experiment was conducted at the Department of Horticulture, Aromatic and Medicinal Plants at Mizoram University for two consecutive years (2012 to 2014). The land exhibits a moderate slope and a satisfactory drainage system. The experimental field was situated at 23°44´15.1´´ N latitudes and 92°39´36.5´´ E longitudes. Agro-climatically, the location represents a humid subtropical hill zone with an annual rainfall of 208 cm. The elevation of the study site was 779 m above the mean sea level. The soil of the experimental site was sandy loam; available N, P and K were 268.45 kg/ha, 19.40 kg/ha and 120.42 kg/ha, respectively, with 0.65% organic carbon present. The soil was acidic with pH of 4.82.

Healthy and disease and pest infestation free tissue cultured seedlings of the Red lady F₁ hybrid was procured from the Directorate of Horticulture, Government of Mizoram Aizawl, Mizoram, India. The experiment was designed in a randomized block design (RBD) with three replications. The secondary hardened tissue cultured seedlings of the Red Lady cultivar of papaya were planted at a spacing of 1.8 × 1.8 m. There were total of 16 treatment combinations as: 

- T₀, Control (water spray); 
- T₁, NAA 100 ppm; 
- T₂, NAA 150 ppm; 
- T₃, NAA 200 ppm; 
- T₄, GA₃ 100 ppm; 
- T₅, GA₃ 150 ppm; 
- T₆, GA₃ 200 ppm; 
- T₇, BA 100 ppm; 
- T₈, BA 150 ppm; 
- T₉, BA 200 ppm; 
- T₁₀, CCC 500 ppm; 
- T₁₁, CCC 750 ppm; 
- T₁₂, CCC 1000 ppm; 
- T₁₃, ethrel 200 ppm; 
- T₁₄, ethrel 300 ppm and 
- T₁₅, ethrel 400 ppm.

The recommended dose of FYM @ 20 tonnes/ha was applied before planting in the respective plots. The recommended dose of N, P2O5 and K2O at 500 g/plant each in the form of urea, single super phosphate and muriate of potash were applied in two split doses, once 2 months after planting and the second at the time of first fruit set in all of the treatments except the control. The plant growth regulators were applied thrice as foliar application 30, 45 and 60 days after planting. Five plants from the middle of each plot were selected randomly and tagged for observation of plant growth characters. The observations on plant growth and yield characters were recorded as standard methods. Percent fruit set was determined as method and formula described by Westwood (1979). Twenty fruits from each treatment were randomly selected to record the data on physico-chemical characters. Fruit size was measured by recording the length and breadth using a digital vernier caliper, whereas fruit weight was taken using top pan digital balance. The fruit volume was measured by the water displacement method and expressed in cc. The organoleptic score was determined by a panel of 10 judges in a 10 point scale based on color and softness of the fruits. The TSS was determined with a Zeiss Hand Brix refractometer (0-32 °B). The titratable acidity, total and reducing sugars and ascorbic acid content were determined by the methods suggested in AOAC (1989).

The pooled data were analyzed using one way analysis of variance (ANOVA) (Gomez and Gomez 1984), and the means were separated with least significant difference analysis using Duncan’s multiple range test (DMRT) at P < 0.05.

RESULTS AND DISCUSSION

Effect of plant growth regulators on the vegetative growth of plants

The effects of various plant growth regulators on the growth parameters of papaya have been enumerated in Table 1. Plant growth regulators exhibited significantly on the vegetative growth of papaya plants. The maximum plant height (123.16 cm), girth (28.73 cm), E-W and N-S spread (215.63 cm and 223.29 cm, respectively) were recorded in control. This might be due to GA3 application at various levels. Data contained in Table 1, revealed that the maximum leaves/plant was recorded with the application of 200 ppm BA, which was significantly higher than other treatments. The maximum number of leaves with BA may be due to an increase in cell division caused by cytokinins and also due to the higher supply of assimilates mediated by BA application (Dwivedi et al. 1999). Our findings are in close conformity with the findings of Singh and Singh (2009), who also reported an increase in leaf number in strawberry plants with BA application.

The significant effect of various treatments on flowering and maturity is displayed in Table 2. Plants treated with 1000 ppm CCC required minimum days to flowering (83.67 days) and maturity (164.67 days). The minimum days to flowering in CCC treated plants may be because CCC promotes the formation and translocation of flowering stimuli as hormones from the leaf to the axils of the leaves and thus produces early flowering compared with other treatments. Our study is in conformity with those of Dwivedi et al. (2002) and Kumar et al. (2012). The early flowering in CCC-treated plants may be due to its role in producing flowers earlier, which might have resulted in early maturity in the CCC-treated plants.

Similarly, among the different treatments, the maximum number of harvests was recorded with the application of 200 ppm GA3, i.e. T6 (19.64). Our study is in close conformity with the findings of Mohammad et al. (1990) and Sharma and Singh (2009), who reported that GA3 application increased the harvesting period.

Effect of plant growth regulators on yield-attributing characteristics

The maximum fruit set percent was obtained with the application of 200 ppm GA3 (76.46%), and the lowest was in the control (47.72%) (Table 2). The application of GA3 resulted in the production of a larger number of flowers with rapid elongation of the peduncle, leading to full development of flower buds exhibiting all functional reproductive parts, which increased fruit set tremendously compared with the control (Voyiatzis and Paroussi 2002). GA also induced the highest number of fruits/plant (72.87). The marked influence of GA on the number of fruits may be attributed to its effects
on better pollen germination and fruit set, which favored the production of a larger number of fruits (Sharma and Singh 2009).

**Effect of plant growth regulators on yield**

Observations pertaining to yield/plant and yield/ha were found to be varied significantly (Table 2). From the perusal of data, GA3 application resulted in the highest yield/plant (86.23 kg) and yield/ha (266.14 tonnes). The increase in yield with gibberellic acid might be due to an increase in flower number, better fruit setting percentage and the production of a higher number of fruits with maximum fruit weight in addition to better vegetative growth. In addition, GA may have affected the auxin metabolism, which may have indirectly aided in fruit enlargement and thus the production of fruits in higher number, which ultimately increases yield/plant and yield/ha (Kappel and MacDonald 2007, Singh and Singh 2006).

**Effect of plant growth regulators on physical parameters of fruits**

The data presented in Table 3 revealed that, GA3 resulted in the maximum fruit length, (20.43 cm), diameter (14.43 cm), circumference (33.32 cm), fruit weight (1 183.34 g), fruit volume (1 423.34 cc), pulp weight (995.31 g) and peel weight (93.56 g). The exogenous application of GA3 increased the cell size of the fruit by the proliferation of the sink demand, resulting in enhanced phloem unloading and carbon assimilate metabolism in the fruit and a greater supply of assimilates and photosynthates to the fruits (Zhang et al. 2007, Ahmed et al. 2012). In addition, GA improved the internal physiology of the developing fruits in terms of a better supply of nutrients and other compounds that are vital for their proper growth and development, which resulted in improved size and ultimately a greater yield (Pandey 1999).

Application with 400 ppm ethrel resulted in fruits that exhibited highest organoleptic score (8.78/10) compared to other treatments. The highest organoleptic score in ethrel treated plants may be because ethrel, as a ripening hormone, increases the sugar: acid ratio and reduces the fruit pressure, which is an index of fruit hardness or softness. The softening of fruit with ethrel may be explained through its action on cell wall hydrolysis and changes in complex substances to simpler ones, which occurs during ripening under the control of ethylene (Jain and Dashora 2011). Ethrel sharply increased the activity of phenylalanine-ammonialyase in treated fruits, which seems to be a determining factor of color development. Similar increases in organoleptic rating, with ethrel, were also reported in apple plants (Singh et al. 2002).

Among the different treatments, the maximum pulp thickness was recorded with 1000 ppm CCC (2.95 cm), and the lowest was in the control (2.18 cm) (Table 3). The increased pulp thickness with CCC might be due to retarded vegetative growths, especially shoot length, and ultimately the accumulation and translocation of metabolites towards the sink (fruit), resulting in thicker pulp (Agrawal and Dikshit 2010). Among the treatments, no significant variation was found with respect to seed number. However, the lowest (377.50) was recorded with gibberellic acid, and the highest was in control (646.80).

**Effect of plant growth regulators on the chemical parameters of fruits**

An inquisition of data presented in Table 4 revealed that application of 400 ppm ethrel resulted in the highest TSS (16.91 %), lowest titrable acidity (0.128 %) and highest total and reducing sugars (10.17 and 7.58%). The increase

</table>
in TSS may be the result of a higher accumulation of metabolites and a quick conversion of starch into soluble sugars during the fruit development in response to growth regulators (Agrawal and Dikshit 2010). The reduction in titratable acidity with ethrel may be due to its action on the fast conversion of organic acids and starch into reducing and non-reducing sugars and their derivatives through higher respiration and carbon assimilation activity during rapid ripening process (Yadav et al. 2001).

Highest ascorbic acid content was found under different concentrations of gibberellic acid, and the lowest was in the control. The perceptive increase in ascorbic acid with gibberellic acid may be due to catalytic influence of ripening of fruits and accelerated activities of hydrolytic enzymes, which is associated with high metabolic changes in fruits, leading to the conversion of complex polysaccharides and organic acids into simple sugars through higher respiration and carbon assimilation activity (Yadav et al. 2001).

</table>
gibberellic acid on its biosynthesis from its precursor glucose-6-phosphate or the inhibition of its conversion to dehydroascorbic acid by ascorbic acid oxidase or both. Similarly, the highest sugar: acid ratio was recorded with the application of 400 ppm ethrel (79.49) and lowest was in control (50.24). Ethrel, a ripening hormone, increases the sugar: acid ratio because of its ability to convert starch to sugars through higher respiration and carbon assimilation activity.
