ABSTRACT

Present research was planned to study incidence, virulence factors viz. biofilm and coagulase production and antibiogram of Staphylococcus aureus associated with bovine mastitis. Milk samples (142) of clinical and subclinical bovine mastitis cases from Mumbai and around Mumbai region were processed. From the milk samples processed; 52 (36.61%) Staphylococcus spp. isolates were recovered. Incidence of S. aureus in bovine mastitis was 28.16% (in cows: 41.37% and in buffaloes: 24.77%). The incidence rate of S. aureus in subclinical and clinical mastitis was 17.24% and 30.97% respectively. The results of antibiotic resistance pattern of isolates indicated highest resistance to penicillin (100%) followed by vancomycin and oxacillin (77.5%) and gentamicin (15%). The least resistance was observed to chloramphenicol (12.5%), ceftriaxone (10%), methicillin and cephotaxim (7.5%). Out of 40 S. aureus isolates characterized for biofilm production, overall 32 (80%) isolates were biofilm producing which were confirmed using various methods, viz. CRA (45%), TCP (35%) and PCR (72.5%) of intercellular adhesin gene ica A and ica D. Of 32 biofilm producing S. aureus, 20 (62.50%) were coagulase producing strains and 65.62% of them also showed biofilm production. Out of 40 S. aureus isolates, 26 (65.00 %) were proved to be coagulase producing strains by tube method; whereas by coa PCR assay, 21 (52.5%) isolates showed presence of coagulase gene. Out of 21 coa exhibiting strains of S. aureus, 4 (10%) isolates were of coa genotype A with an ampiclon size of 850 bp while 17 (42.5%) S. aureus isolates were of genotype B with an ampiclon product of 600 bp. Out of 26 coagulase producing S. aureus, 21 (80.76%) were biofilm producing. Most of biofilm and coagulase producing strains displayed multiple drug resistant.

Key words: Biofilm, Bovine mastitis, Coagulase, Staphylococcus aureus

Mastitis alone causes approximately 70% of all avoidable losses incurred during milk production. The total economic losses per annum due to clinical and sub-clinical mastitis (SCM) in India are reported to be ₹ 6,038.7 and ₹ 2,345.5 million, respectively (Dua 2001).

While a several types of bacterial pathogens are responsible for this condition, Staphylococcus aureus is the principal cause accounting more than 19-40% cases (Kumar et al. 2004). The type of mastitis produced by S. aureus ranges from subclinical to peracute life threatening form, one of which is gangrenous mastitis.

S. aureus possesses a wide array of virulence factors, occurrence of Staphylococcal biofilms in the bovine udder was reported (Vasudevan et al. 2003, Cucarella et al. 2004, Fox et al. 2005), which raises concerns about the success of antibiotic therapy of persistent Staphylococcal infections by preventing penetration of many antibiotics (Thien and O’toole 2001) and even antibodies and thus allowing bacterial survival at high antimicrobial concentrations (Oliveira et al. 2006). The intercellular adhesion (ica) locus consisting of the genes ica ADBC encodes the proteins mediating the synthesis of polysaccharide intercellular adhesin (PIA) and polysaccharide/adhesin (PS/A) in Staphylococcal species (Cramton et al. 1999, Borriello et al. 2005). Among ica genes, the ica A and ica D play a significant role in biofilm formation in S. aureus (Yazdani et al. 2006), ica A gene encodes N-acetylglucosaminyl transferase. Further, ica D plays an important role in expression of this enzyme (Arciola et al. 2001).

S. aureus exhibits virulence by producing coagulase enzyme that converts fibrinogen to fibrin and clots plasma around the cells which protect S. aureus from defence mechanisms, thereby helping in their survival and multiplication. Production of coagulase, a product of coagulase (coa) gene, is the principal criterion used in identification of pathogenic S. aureus. The amplification of the coagulase gene (coa gene) is considered as a simple and accurate method for identifying and discriminating S. aureus strains. Systematic study on incidence and characterization of Staphylococcus aureus strains associated
with mastitis is planned in the present research.

MATERIALS AND METHODS

Isolation and identification of S. aureus

Milk samples (142) from clinical and sub-clinical cases of bovine mastitis cases from organized farm as well as unorganized sectors located in and around Mumbai were processed for isolation on S. aureus selective medium i.e. mannitol salt agar (MSA). Inoculated plates were incubated at 37°C for 24 h and examined for appearance of typical growth suggestive of S. aureus.

Isolates which grew on MSA showing mannitol fermentation were further inoculated on nutrient agar (NA) Baird Parker agar (BPA) and blood agar. Isolates showing golden pigment production on NA and black, shiny, convex colonies of 1-5 mm in diameter with a narrow, white edge surrounded by a clear zone 2-5 mm wide.Opaque rings within the clear zones appeared after 48 h of incubation on BP and hemolytic colonies on blood agar. Isolates showing fermentation were further inoculated on nutrient agar (NA) and tissue culture plate (TCP) assay.

In vitro antibiotic sensitivity test

All isolates of S. aureus were subjected to in vitro antibiotic sensitivity test by single disc diffusion method (Bauer et al. 1966). Commercially available discs of 8 suitable antibiotics methicillin, oxacillin, penicillin–G, ceftriaxone, cephotaxime, gentamicin chloramphenicol and vancomycin were selected to test the sensitivity of 40 S. aureus isolates.

Detection of biofilm production by S. aureus

Phenotypic detection of biofilm production of S. aureus was carried out by following 2 conventional methods, viz. Congo red agar (CRA) method and tissue culture plate (TCP) assay.

Congo red agar (CRA) method: Qualitative detection of biofilm production by S. aureus was carried out by using the Congo red agar (CRA) method (Vasudevan et al. 2003). CRA plates were inoculated with S. aureus isolates and incubated aerobically for 24 h at 37°C followed by subsequent storage at room temperature for 24 h. A positive result was indicated by black colonies with a dry crystalline consistency. Non-slime producers remained red with smooth or dry crystalline colonial morphology. The cultures were tested thrice on CRA for biofilm production and results were taken.

Tissue culture plate (TCP) assay: The detection of biofilm production by TCP assay was performed as per Mathur (2006). S. aureus strains were grown overnight in TSB (trypticase soy broth) with 1% glucose at 37°C. The cultures were diluted 1:100 in TSB with 1% glucose and 200 µl of this cell suspension was inoculated in wells of sterile 96-well polystyrene microtiter plate in triplicate.

After 24 h incubation, the wells were gently washed 3 times with 200 µl of sterile PBS, dried in an inverted position and stained with 0.1% safranin for 30 sec. Wells were rinsed again for 3 times with sterile distilled water, and the absorbance (OD) was taken at 490 nm. Readings were taken as per Table 1 and isolates showing the strong and moderate adherence/biofilm production were taken as positive.

Genotypic characterization of S. aureus for biofilm production

DNA extraction: Chromosomal DNA of S. aureus was extracted as per Wilson (1987) with some modifications. Overnight grown broth culture of S. aureus was centrifuged at 12,000 rpm for 10 min. The pellets were dissolved in each of 200 µl TE buffer and 50 µl of 50 mg/ml stock solution of lysozyme. Vortexed and incubated for 2 h at 37°C. Sodium dodicyl sulphate (SDS 10%) in 30 µl quantity and 80 µl of 20 µg/ml stock proteinase K was added, vortexed and incubated for 1 h at 65°C. NaCl 5M in 100 µl quantity was added, vortexed and 80 µl of C-TAB/NaCl solution (10% cetyl-tri-methyl ammonium bromide in 0.7 NaCl) was added, mixed properly and incubated at 65°C for 30 min. Equal amount of phenol:chloroform (1:1) was added, vortexed for 2-3 min and centrifuged at 12,000 rpm for 10 min. Upper aqueous phase was transferred to sterile microcentrifuge tube to which equal amount of chloroform:isoamyl alcohol (24:1) was added, mixed and centrifuged at 12,000 rpm for 10 min. then transferred to sterile microcentrifuge tube. Precipitation of DNA from upper aqueous phase was done by using one-third volume of 7.5 M ammonium acetate and double volume of chilled absolute ethanol. The samples after storage at –20°C for overnight were centrifuged; the pellets were washed with 70% ethanol and air-dried. The pellets were resuspended in 30 µl of sterile nuclease free water (NFW) and incubated in water bath at 65°C for 2 h. The preparation was stored at –20°C and used for PCR.

The isolated DNA samples were subjected to electrophoresis in ethidium bromide stained agarose gel for assessing their integrity as per Brown (2007). The integrity of DNA was checked by visualization of the DNA using UV transilluminator.

Detection of biofilm producing intercellular adhesion genes (ica) by PCR

PCR was carried out for detection of intercellular adhesion genes responsible for biofilm production, viz. ica A and ica D as per Vasudevan et al. (2003). The primers used for PCR of the intercellular adhesion genes (ica A and

ica D) were synthesized and procured commercially (Table 2).

**Reaction mixture and cycling conditions:** The reaction mixture set in total 25µl quantity and the PCR mixtures were spun briefly in PCR tubes (0.2 ml) and set into an automated thermal cycler. The cycling conditions included an initial denaturation at 94°C for 3 min followed by 40 cycles each of denaturation at 92°C for 45 sec, annealing at 49°C for 45 sec and extension at 72°C for 1 min, followed by final extension of 7 min at 72°C. The PCR products were further analysed for their molecular weight by agar gel electrophoresis (AGE).

**Phenotypic and genotypic characterization of S. aureus for coagulase production**

**Coagulase test:** Phenotypic characterization by tube coagulase test was carried out as per Sperber (1975) with slight modification. Each fresh overnight culture of S. aureus isolate prepared in brain heart infusion broth (BHI) was inoculated in 0.2 ml quantity separately in 0.5 ml of rabbit plasma and incubated at 37°C. The tubes were examined for the formation of clots at 2, 4 and 24 h intervals. The reactions were interpreted as 4+ reaction where very firm, opaque clot was formed and remained in place when the tube was tipped on its side. The typical 1+, 2+ and 3+ reactions were not as opaque as the 4+ reaction and were surrounded by clear plasma.

**PCR of coa gene of S. aureus:** Chromosomal DNA of S. aureus was extracted as per Wilson (1987) with some modifications as mentioned under biofilm production. PCR amplification of coagulase gene (coa) of S. aureus was done as per Hookey et al. (1998). The primers used for the coagulase gene (coa) PCR (Table 3) were synthesized and procured commercially.

**Reaction mixture and cycling condition:** The PCR was set in total 25 µl reaction volume and PCR mixtures were spun briefly in PCR tubes (0.2 ml) and set into an automated thermal cycler. The cycling condition included an initial denaturation at 94°C for 5 min followed by 30 cycles each of 40 sec denaturation at 94°C, 1 min annealing at 58°C and 1 min extension at 72°C, followed by final extension of 10 min at 72°C. The PCR products were further analysed for their molecular weight.

Amplified products of coa genes were evaluated by agarose gel electrophoresis was carried out in submarine electrophoresis apparatus at 12 V/cm and the product was visualized and documented using automatic computerized gel documentation and analysis system and the size of PCR product generated was determined.

**RESULTS AND DISCUSSION**

In the present research work, isolation of Staphylococcus aureus from clinical and sub-clinical cases of bovine mastitis and their characterization for coagulase and biofilm production was carried out using conventional bacteriological and molecular techniques.

Isolation of Staphylococcus spp. was carried out on mannitol salt agar and identification of S. aureus isolates recovered from milk samples was done using conventional bacteriological techniques like growth characteristics on various media (Table 4), morphology and staining characters, biochemical and sugar fermentation tests.

**Incidence of S. aureus in bovine mastitis**

Bovine mastitis is responsible to cause economic loss to the dairy industry world over. Although, a number of microbial species are known to be associated with this condition, Staphylococcus aureus is the principal reported cause of mastitis.

Out of 142 (29 cows and 113 buffaloes) milk samples isolates was done as per Hookey et al. (1998). The primers used for the coagulase gene (coa) PCR (Table 3) were synthesized and procured commercially.

from the cases of clinical and subclinical bovine mastitis processed, 52 (36.61%) isolates of *Staphylococcus* spp were recovered with an incidence rate of 16 (55.17%) and 36 (31.85%) *Staphylococcus* spp. from cows and buffaloes respectively.

Out of 52 Staphylococcal isolates recovered, 40 isolates were confirmed as *S. aureus* based on various identification criteria, while remaining 12 were proved to be the other *Staphylococcus* species. Whereas, from 29 samples of cows and 113 samples from buffaloes, 12 (41.37%) and 28 (24.77%) were confirmed as *S. aureus* respectively (Table 5). The incidence of *S. aureus* in clinical and subclinical mastitis was 30.97 and 17.24% respectively.

Rate of incidence of *Staphylococcus* spp observed in the present study laid between the incidence rate observed by Rao et al. (1989) wherein they reported 30.3% of *Staphylococcus* spp. in bovine mastitis, whereas Dhote et al. (1999), Khesar (2006) and Chavan (2007) reported 41, 43.47 and 42% incidence of *Staphylococcus* spp. respectively from bovine mastitic milk.

In the present study *S. aureus* was recovered from 28.16% cases of mastitic milk samples. The similar ranges, i.e 26.20 and 26.24% of recovery of *S. aureus* from mastitic milk samples was reported by Takeshinge et al. (1983) and Kalorey et al. (2007) respectively. Higher rate, i.e. 82.1% was reported by Roberson et al. (1996), whereas lower incidences of *S. aureus* in bovine mastitis, i.e. 19 and 15.67% were reported by Njau and Kundy (1985) and Saei et al. (2009) respectively. The rate of incidence found in present study laid between the ranges of incidence observed by various authors.

Incidence of *S. aureus* in the present study of clinical and subclinical mastitis was found to be 30.97 and 20.68% respectively. The results of incidence of clinical mastitis due to *S. aureus* in present study laid between incidence reported by Wani and Salmon (2003) and Sumathi et al. (2008) who observed 45 and 24% incidence of *S. aureus* respectively from cows with clinical mastitis. Whereas, Getahun et al. (2007) observed higher (42.6%) prevalence of *S. aureus* in sub-clinical mastitis. The observations of higher incidence rate of *S. aureus* in clinical than in subclinical mastitis of present study are in correlation with Cheng et al. (2010) who reported that *S. aureus* was more (41%) frequently associated with clinical mastitis than subclinical case.

In vitro antibiotic sensitivity test

All organisms vary in their susceptibility to antibiotics therefore antibiotic gram typing, which involves determining susceptibility to battery of antimicrobials is a widely used phenotypic method for characterization of *S. aureus* associated with bovine mastitis (Myllys et al. 1998, Osteras et al. 2006). The method can be useful for initial screening of multiresistant strain and assist in application of suitable antibiotics leading to proper treatment.

Out of 40 isolates of *S. aureus*, 3 (7.5 %) isolates were resistant to methicillin (M) and cefotaxime (CE), 4 (10%) to ceftriaxone (Cl), 5 (12.5%) to chloramphenicol (C), 6 (15 %) to gentamycine (GM), 31 (80 %) to oxacillin (OX) and vancomycin (VA), whereas all isolates (100%) were resistant to penicillin (P) (Fig. 1).

The similar results of high (100%) resistance pattern to penicillin group was observed by Turatoglu and Mudul (2003), Guler et al. (2005), Ahmadi et al. (2008) and Shi et al. (2010). The resistance patterns to methicilne 7.5% obtained was totally in accordance with Chavan (2007). The least resistance to gentamycin and chloramphenicol, i.e. 15 and 12.5%, respectively correlated with the findings of Khesar (2006), Ahmadi et al. (2008) and Sumathi et al. (2008) who observed gentamicin and chloramphenicol as useful drug against *S. aureus*. The cephotaxim and ceftriaxone were found to be most effective antibiotics in the present study (Amorena 1999).

Multiple drug resistance was observed in all isolates of cows and buffaloes except in 5 isolates of buffaloes. Out of 3 methicillin resistance strains one was from cow and 2 were from buffaloes which were also resistant to other penicillin group, i.e. VA, OX and P. All 3 methicillin resistance strains were strong biofilm producers whereas, one was coagulase positive (CPS) and 2 were coagulase negative (CNS).

**Phenotypic characterization of biofilm producing S. aureus strains**

*Congo red agar (CRA) method:* All 40 *S. aureus* isolates screened thrice for detection of biofilm production on CRA.
Out of 40 isolates, 18 (45%) showed black colonies with a dry crystalline consistency suggesting biofilm production. In cows 6 (50%) out of 12 and in buffaloes out of 28, 12 (42.85%) S. aureus isolates were biofilm producing. Out of total 18 positive isolates tested by CRA, 2 isolates were negative for ica gene.

The results of biofilm production by CRA method in 18 (45%) isolates of S. aureus laid between the ranges recorded by Oliveira et al. (2006) and Dhanavade et al. (2009), i.e. 37.5 and 48.05% respectively, although reports of higher percentage (91.42%) was also recorded by Vasudevan et al. (2003).

Tissue culture plate (TCP) method: Out of 40 isolates tested by tissue culture plate (TCP) method, 14 (35%) were biofilm producing. Out of total 14 positive isolates, 11 (78.57%) isolates gave strong biofilm formation (6 from cow and 5 from buffalo) whereas, 3 (21.42%) isolates were moderate biofilm producers (2 from cow and 1 from buffalo). Out of 14 positive isolates tested by TCP, 1 isolate was negative for ica gene.

Out of 40 isolates, 18 (45%) showed black colonies with a dry crystalline consistency suggesting biofilm production. In cows 6 (50%) out of 12 and in buffaloes out of 28, 12 (42.85%) S. aureus isolates were biofilm producing. Out of total 18 positive isolates tested by CRA, 2 isolates were negative for ica gene.

The results of biofilm production by CRA method in 18 (45%) isolates of S. aureus laid between the ranges recorded by Oliveira et al. (2006) and Dhanavade et al. (2009), i.e. 37.5 and 48.05% respectively, although reports of higher percentage (91.42%) was also recorded by Vasudevan et al. (2003).

Tissue culture plate (TCP) method: Out of 40 isolates tested by tissue culture plate (TCP) method, 14 (35%) were biofilm producing. Out of total 14 positive isolates, 11 (78.57%) isolates gave strong biofilm formation (6 from cow and 5 from buffalo) whereas, 3 (21.42%) isolates were moderate biofilm producers (2 from cow and 1 from buffalo). Out of 14 positive isolates tested by TCP, 1 isolate was negative for ica gene.

The abundant studies on biofilm production were carried out more in medical fields than in veterinary and the reports of recovery of 57.10 and 57.80% of biofilm producing strains by Johannes et al. (2002) and Mathur et al. (2006), respectively, from human infections and medical devices are observed at higher range than the findings of biofilm formation in 14 (35%) isolates of present study. The results of above 2 phenotypic methods were correlated, although CRA was found slightly more sensitive than TCP method.

Genotypic characterization of biofilm producing S. aureus strains

The extracted DNA showing good integrity were subjected to PCR for amplification of ica gene, i.e. ica A and ica D genes. Out of 40 isolates of S. aureus, 29 (72.5%) were positive to ica A with an amplicon of 1315 bp (Fig. 2) and ica D gene with amplicon size of 381 bp (Fig. 3). The PCR method was more sensitive than CRA and TCP method for detection of biofilm producing strains (Table 6, Fig. 4).

By PCR method of intercellular adhesion gene amplification, 29 (72.5%) S. aureus isolates were positive for both ica A and ica D genes. Higher (100%) prevalence of intercellular adhesion genes namely ica A and ica D from S. aureus of bovine mastitic origin were reported by Vasudevan et al. (2003). The importance of intercellular adhesion genes (ica AD) in biofilm production were detected in S. aureus recovered from human medical devices by Crumpton et al. (1999), Arciola et al. (2001) and Yazdani et al. (2006). This also indicated important role of biofilm in pathogenesis of infections caused by S. aureus.

*Figures in parentheses indicate percentage.*
Out of 32 biofilm producing isolates, 29 isolates possessed both ica A and ica D genes, whereas 3 isolates which were positive for biofilm production by CRA and TCP method did not possess ica A and ica D genes. Several workers have investigated the biofilm production in S. aureus and other Staphylococci, by using phenotypic and molecular techniques. Chaieb et al. (2005) investigated the biofilm production in S. epidermidis employing CRA and PCR of ica A and ica D genes and observed that one strain, which was negative for presence of ica A and ica D genes was phenotypically positive.

The findings of present study of biofilm producing ability of 2 isolates in absence of ica A and ica D genes is in agreement with that of Chaieb et al. (2005). Our results further supported by the observation of Liberto et al. (2006) who reported 79.3 % concordance between the slime production and presence of ica A and ica D. Dhanawade et al. (2009) studied biofilm production in S. aureus by different methods and observed greater numbers of isolates positive by Congo red agar than by PCR of ica A and ica D genes.

In present investigation, total 32 (80%) isolates proved to be biofilm producing by both phenotypic and genotypic methods of identification of biofilm producing S. aureus. Out of 32 biofilm producing S. aureus, 20 (62.50%) were coagulase producing stains and most (65.62%) of them displayed multiple drug resistance.

### Phenotypic and genotypic characterization of coagulase producing S. aureus strains

#### Tube method

Out of 40 S. aureus isolates tested for coagulase production by tube method using rabbit plasma, 26 (65%) were proved to be positive for coagulase production while 14 (35%) turned out to be coagulase negative (Fig. 5). In cows out of 12 isolates, 11 (91.66%) were CPS, whereas in buffaloes out of 28 isolates, 15 (53.57%) were CPS.

Out of 26 isolates tested positive by tube method, 21 exhibited coa gene, whereas 5 isolates were lacking coa gene (Table 7). Out of 26 coagulase producing S. aureus 21 (80.76%) were biofilm producing and most (88.46%) of them displayed multiple drug resistant.

In present study out of 40 S. aureus isolates, 26 (65%) were coagulase producing strains (CPS) by tube method. Higher ranges of CPS strains were reported by Baker et al. (1985) and Khesar (2006), i.e. 92.5 and 84.78%, respectively, by similar method. Whereas, lower percentages, i.e. 57.14 and 47.05 % CPS isolates were also observed by Hussain et al. (2002) and Chavan (2007) respectively. The range of CPS recovered in present study laid between the ranges observed by the above authors.

#### Detection of coagulase gene (coa) by PCR

Out of 40 isolates of S. aureus subjected to PCR for amplification of coa gene, 21 (72.5%) possessed coa gene. Of 21 S. aureus isolates tested positive for coa gene, 4 (10%) were of genotype A, which generated an amplicon of 850 bp.

bp, whereas 17 (42.5%) \textit{S. aureus} isolates yielded an amplification product of 600 bp suggestive of genotype B. Only 2 types of genotypes of \textit{coa} gene were observed in 21 isolates originated from different locations in and around Mumbai (Table 8; Fig 7).

The findings of present study concerning existence of different \textit{coa} genotypes among \textit{S. aureus} isolates are in accordance with those of many other workers who have observed prevalence of multiple \textit{coa} genotypes among the \textit{S. aureus} strains. Hookey et al. (1998) observed 4 different \textit{coa} PCR types among the \textit{S. aureus} strains tested that yielded amplification products of 875, 660, 603 and 547 bp. Thus results of molecular characterization matched with the result of authors quoted by da Silva et al. (2005) who reported 10 different \textit{coa} PCR types. The amplification products generated in their studies ranged from 484 to 1080 bp. Grzegorczyk et al. (2006) while studying the \textit{S. aureus} isolates from nasal mucosa of children encountered 4 different \textit{coa} genotypes with amplicon sizes of 600, 700, 750 and 800 bp. Kalorey et al. (2007) while detecting genes encoding virulent determinants of \textit{S. aureus} from subclinical mastitis recorded 3 \textit{coa} PCR types generating amplification products of 627, 710 and 910 bp. Karahana and Cetinkaya (2007) reported PCR of \textit{coa} gene produced amplicon ranging from 500 to 1400 bp.
