**Key words:** *Channa striatus*, Copper sulphate pentahydrate, Formalin, Hatching rate, Hydrogen peroxide, Survival

Striped murrel, *Channa striatus* is a native freshwater fish of tropical Africa and Asia. Bacterial and fungal diseases are major threat to murrel eggs. In particular, Aquatic fungus (Saprolegniales) ubiquitous in natural water, often cause serious diseases in fishes and their eggs. Bacterial infections are common to hatcheries with temperature higher than 28°C whereas fungal infections are prevalent below 26°C. At this juncture, management techniques viz., temperature manipulation, jar-hatching of eggs with adhesive matrix removed, sanitation and aeration are helpful in minimizing fish mortality but not cent percent cure is assumed. Mechanically removing dead and infected eggs will be time consuming and chemical treatments can be proved effective. The beneficial effects of various disinfectants were evaluated by aquaculturists of different countries using different fish species viz., hydrogen peroxide by Rach *et al.* (1998) in warm and cold water fishes, hydrogen peroxide by Mitchell *et al.* (2009) in channel catfish, formalin by Akpoilih and Adebayo (2010) in African catfish and copper Sulfate by Straus *et al.* (2011a, b, c) in channel catfish. As there is a continued need for therapeutants to control fungal infestations, aquatic fungicides viz. formalin, hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and copper sulphate (CuSO<sub>4</sub>. 5H<sub>2</sub>O) were investigated in the present study.

Ten pairs of gravid *C. striatus* (700 – 800 g mean weight) were selected and acclimatized without food in four fibre tanks (1m × 1m × 1 m) with a density of 3 fish per tank at CARE Aquafarm. Brooders were injected with natural hormone, human chorionic gonadotrophin (HCG) at 4,000 IU/kg and allowed to spawn. Fertilized egg masses were collected and sorted out as 150 healthy eggs per tank filled with 500 L of water at 28°- 30°C, for treatments with formalin, hydrogen peroxide and copper sulphate each with

triplicate for 15 min exposure time (Table 1). Hatching and survival rates were calculated as follows:

$$\% \text{ hatching rate} = \text{Number of hatched eggs} / \text{Total number of eggs} \times 100.$$

$$\% \text{ survival} = \text{Number of larvae alive} / \text{total number of hatched larvae} \times 100.$$

Following egg disinfection, 0.2 ml of eggs was subjected to fungal and bacterial counting on plates containing nutrient agar and czapadox agar respectively. Percentage of egg hatching, larval survival to first feeding, larval size at hatching and number of microbial colonies were compared using ANOVA and Tukey's multiple comparison test. All percentages were appropriately transformed using arc sin-square root. The statistical software package STATISTICA was used.

H<sub>2</sub>O<sub>2</sub> and Cu75 treatments resulted in the lowest egg hatching rates (P<0.05) compared with the other treatments; whereas F60 showed the highest hatching rate (82.1%) and survival rate (90.5%) (P>0.05). Fry started to hatch after 24h, and hatching was over by 48 h. Most of the F60 treated eggs hatched (> 82%) by day 3, but the other treatments resulted in <60% hatching. Fry survival in the control was only 25% whereas 90.5±3.5 % survival was noticed in 60 mg/L Formalin treatment and the difference in survival was significant between treatments (P=0.005).

Mitchell *et al.* (2009) reported that treatments of eggs with 2000 mg/l H<sub>2</sub>O<sub>2</sub> and above caused complete egg

mortality, while treatment with 1,000 mg/L  $H_2O_2$  resulted in 11% survival. However, Rach *et al.* (1998) reported survival of 78%, 68% and 0% at 1,000, 3,000 and 6,000  $\mu$ l/l  $H_2O_2$ , respectively.

The high concentration of  $CuSO_4$  (Cu100) was toxic to eggs of *C. striatus*. In addition to the low cost of  $CuSO_4 \cdot 5H_2O$ , it does not have the human health implications or storage precautions associated with hydrogen peroxide or formalin. Several reasons can be suggested for the difference in hatching rates viz. susceptibility of an individual spawn to saprolegniasis, the number of unfertilized eggs in an individual spawn and other pathogens infecting an individual spawn (e.g., bacteria, ciliates).

As tabulated (Table 2), no bacterial colonies were detected among treatments Cu75 and Cu100. For the different treatments regarding bacterial load, there was a significant difference ( $P < 0.05$ ) between the control and the treated groups. In previous effectiveness studies under similar conditions, control showed hatching rate of 2% (Straus *et al.* 2009a), 8% (Straus *et al.* 2009b) and 4% (Straus *et al.* 2011). Leonard *et al.* (2000) reported that recirculating systems released approximately  $10^4$  cfu ml into the rearing medium and the UV disinfection unit kept the number of bacteria stable. Ozonation has been frequently used for pre-treating water supply to fish farms where water-borne pathogens are significant problems (Summerfelt 2003).

Eggs treated with formalin showed the highest hatching rate and larval survival rate for each treatment. The F100 treatment has been used successfully in the culture of other freshwater fishes such as *Clarias gariepinus* (Akpoilih 2010).

The high dosage treatment of formalin produced a better hatching rate than other antifungal agents, although, the effective concentration that can be used depend on the time of application, type of fish and kind of parasite targeted (Herwig 1979). There were significant differences in the hatching and survival rates of early larvae between the control and all 4 formalin concentrations ( $P < 0.05$ ), but the

application of 100 mg/l of  $CuSO_4 \cdot 5H_2O$  resulted in total egg mortality (0% hatching rate). Because of the highest survival and hatching rates, formalin (F60) is recommended for farm use.

## SUMMARY

The effect of formalin, hydrogen peroxide and copper sulphate pentahydrate on the hatching rate of eggs of the striped murrel, *Channa striatus* and subsequent survival of the larvae were investigated using range finding and definitive tests. Four treatments were used to define the threshold limit of tolerance of eggs to formalin, hydrogen peroxide and copper sulphate pentahydrate. There were significant differences in the hatching rate and survival of early larvae between the control and all four formalin.

## ACKNOWLEDGMENT

We acknowledge the financial assistance received from Indian Council of Agricultural Research – National Agricultural Innovation Project (ICAR-NAIP F.No. 1(5)/2007-NAIP dt. 22 August 2008) to carry out this study. We are grateful to Rev. Dr. A. Joseph, S.J., Principal and Consortium Leader, for providing necessary facilities.

# NUTRIENT REQUIREMENTS OF ANIMALS

A nutritionally balanced 'livestock feed basket' improves the productivity of animals and simultaneously the economic condition of animal keepers. Feed requirement varies from species to species and from one geographic zone to another depending upon the animal potential and plant-soil-animal relationship. Several institutes of the Indian Council of Agricultural Research, have been working on these crucial aspects of animal nutrition since their inception. Earlier, ICAR published Nutrient Requirement of Livestock and Poultry in 1985 and 1998. Changing climate, vegetation cover and expectations of human population from animal resources have greatly affected the animal sector scenario. Realizing the fact that detailed information is required on nutrient composition of various feeds and fodders, the Council constituted a National Committee on Nutrient Requirements of Animals for compilation of information generated by these institutes.

In this present attempt the Committee has brought out 'Nutrient Requirements of Animals' – a series of ten publications. For the first time nutrient requirements of Camel, Yak and mithun, Companion, laboratory and captive wild animals besides Finfish and shellfish have been compiled. This series will be a must reference resource for livestock policy-framers, researchers, academicians, extension officials and grassroot farmers who steer positive changes in the societies' nutritional security and social integration.
